

Tutorial: NMIS8, adding a new threshold

1. Overview

NMIS8 includes powerful capabilities for performance and operational thresholding, which greatly enhance network management capabilities. These thresholds result in alerts/events/notifications which NMIS can send when it sees a threshold breached. The thresholds have very granular controls which by default have been configured fairly broadly.

In this tutorial, we will walk you through creating a new threshold for the "System Load Avg" of a currently installed device on NMIS8.

What you'll learn

- How to use the common threshold configuration.
- How to create a new threshold for a device.
- The association and dependencies between configuration files.

What you'll need

- Our Opmantek Virtual Appliance (VM) from [Opmantek.com](https://opmantek.com)

Background Information

The Linux system load is a measurement of the computational work the system is performing. A completely idle computer has a load average of 0. Each running process either using or waiting for CPU resources adds 1 to the load average. So, if your system has a load of 5, five processes are either using or waiting for the CPU.

On its own, the load number doesn't mean too much. A computer might have a load of 0 one split-second, and a load of 5 the next split-second as several processes use the CPU. Even if you could see the load at any given time, that number would be basically meaningless.

That's why Unix-like systems don't display the current load. They display the load average. This allows you to see how much work your computer has been performing.

It is important to clarify that on Linux at least, the load average and CPU utilisation are actually two different things. Load average is a measurement of how many tasks are waiting for the CPU (not just CPU time but also disk activity) over a period of time. CPU utilisation is a measure of how busy the CPU is right now. The most load that a single CPU thread pegged at 100% for one minute can "contribute" to the 1 minute load average is 1. A 4 core CPU with hyper-threading (8 virtual cores) all at 100% for 1 minute would contribute 8 to the 1 minute load average.

If you are not familiar with these concepts, here you can find detailed information about [Understanding Linux CPU Load](#) and [Linux Load Averages](#).

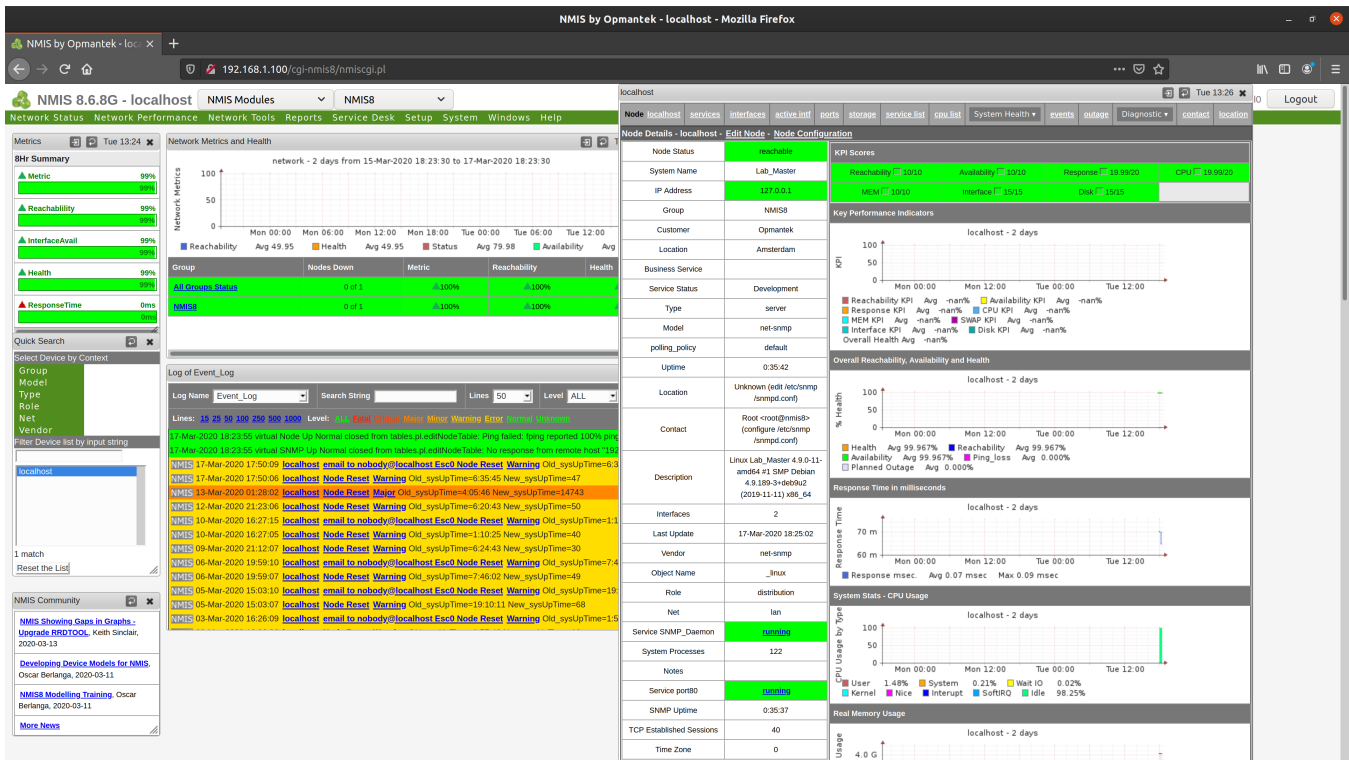

2. Set up your environment

If you haven't done it yet. Download our latest Virtual Appliance from [Opmantek.com](https://opmantek.com)

Import it into your favourite hypervisor, run the VM and get the IP address assigned to it.

For this tutorial, my NMIS8 environment is using 192.168.1.100, this IP address may be different on your set up.

NMIS adds the server where it is hosted as "localhost" and the model used is "Net-snmp", the model and the related files are usually stored in: /usr/local/nmis8/models/

You need to access the VM via SSH to edit the configuration files, the default credentials for the VM are:

```
username: root
password: NM1$88
```

Important

It is important to verify the syntax of the edited files, remember to use: `perl -c filename` after saving the changes.

3. Creating a new threshold

As mentioned before, we will be creating a threshold for the Linux "System Load Averages", we want to generate events when current values exceed the threshold.

Load Averages

Start

Node

Type

End

Interface

[NMIS](#) [IP](#) [Health](#) [Response](#) [Stats](#) [Export](#) [Adv. Export](#)

Clickable graphs: Left -> Back; Right -> Forward; Top Middle -> Zoom In; Bottom Middle -> Zoom Out, in time

First, we need to open the Model, in this case /usr/local/nmis8/model/Model-net-snmp.nmis and identify the item that we need to modify.

The item to modify is "laload" (Linux Average Load) that is under the "system rrd" section.

```

60 },
61
62 'system' =>
63 {
64   'nodeModel' => 'net-snmp',
65   'nodeVendor' => 'net-snmp',
66   'nodeType' => 'server',
67   'nodegraph' => 'health,response,ss-cpu,Host_Memory,ss-blocks,hrcsystem,ip,tcp-conn,tcp-segs,laload,hrcmpcpu,hrcmem,hrcachemem,hrcbufmem,hrcswapmem,hrcvmem',
68
69   'sys' =>
70   {
71     'standard' =>
72     {
73       'laload' => {
74         'snmp' => {
75           'laload1' => {
76             'oid' => 'laload.1',
77           },
78           'laload5' => {
79             'oid' => 'laload.2',
80           }
81         }
82       },
83       'alerts' => {
84       },
85       'rrd' => {
86         'nodehealth' => {
87         },
88         'tcp' => {
89         },
90         'laload' => {
91           'graphtype' => 'laload',
92           'snmp' => {
93             'laload1' => {
94               'oid' => 'laload.1',
95               'option' => 'gauge,0:U'
96             },
97             'laload5' => {
98               'oid' => 'laload.2',
99               'option' => 'gauge,0:U'
100            }
101          }
102        },
103        'systemStats' => {

```

On the "laload" item we have to add the "threshold" item as follow:

```
'threshold' => 'laload_threshold',
```

In this particular case, we have named the threshold "laload_threshold" to make it more noticeable and to be more clear, however this is not a rule.

/usr/local/nmis8/model/Model-net-snmp.nmis

```
--snip--
'laload' => {
  'threshold' => 'laload_threshold',
  'graphtype' => 'laload',
  'snmp' => {
    'laLoad1' => {
      'oid' => 'laLoad.1',
      'option' => 'gauge,0:U'
    },
    'laLoad5' => {
      'oid' => 'laLoad.2',
      'option' => 'gauge,0:U'
    }
  }
},
--snip--
```

```
168 },
169 'rrd' => {
170   'nodehealth' => {
180   },
181   'tcp' => {
225   },
226   'laload' => {
227     'threshold' => 'laload_threshold',
228     'graphtype' => 'laload',
229     'snmp' => {
230       'laLoad1' => {
231         'oid' => 'laLoad.1',
232         'option' => 'gauge,0:U'
233       },
234       'laLoad5' => {
235         'oid' => 'laLoad.2',
236         'option' => 'gauge,0:U'
237       }
238     }
239   },
```

We add the threshold values to /usr/local/nmis8/models/Common-threshold.nmis, using the name specified before. The event name must include "Proactive" at the beginning.

```

%hash = (
  'threshold' => {
    'name' => {
      'laload_threshold' => {
        'item' => 'laLoad5',
        'event' => 'Proactive System Load',
        'select' => {
          'default' => {
            'value' => {
              'fatal' => '5',
              'critical' => '2',
              'major' => '1',
              'minor' => '0.8',
              'warning' => '0.7'
            }
          }
        }
      }
    }
  },
  --snip--

```

```

Common-threshold.nmis x
1 %hash = (
2   'threshold' => {
3     'name' => {
4       'laload_threshold' => {
5         'item' => 'laLoad5',
6         'event' => 'Proactive System Load',
7         'select' => {
8           'default' => {
9             'value' => {
10              'fatal' => '5',
11              'critical' => '2',
12              'major' => '1',
13              'minor' => '0.8',
14              'warning' => '0.7'
15            }
16          }
17        }
18      },
19      'qos3gTeldat' => {
20        'item' => 'rxLevelTeldat',
21        'event' => 'Proactive Teldat low level',
22        'title' => "Low level of mobile power",
23        'unit' => "dBm",

```

Next we add statistics extraction to /usr/local/nmis8/models/Common-stats.nmis

Adding it inside the "type" section.

- In green, we have to use the name used in the /usr/local/nmis8/models/Common-database.nmis, because the stats need to know which database to read.
- In blue, the name of the 'item' holding the variable, see 'item' in blue box in the Common-stats.nmis picture above.
- In magenta, the name of the data source specified in the model inside the rrd section, in this case is "laLoad5"

```

Common-stats.nmis x
32 %hash = (
33   'stats' => {
34     'type' => {
35       'laload' => [
36         'DEF:laLoad5=$database:laLoad5:AVERAGE',
37         'PRINT:laLoad5:AVERAGE:laLoad5=%1.2lf'
38       ],
39     'calls' => [
40       'DEF:DS0CallType=$database:DS0CallType:AVERAGE',
41       'DEF:L2Encapsulation=$database:L2Encapsulation:AVERAGE',
42       'DEF:CallCount=$database:CallCount:AVERAGE',
43       'DEF:AvailableCallCount=$database:AvailableCallCount:AVERAGE',
44       'DEF:totalIdle=$database:totalIdle:AVERAGE',
45       'DEF:totalUnknown=$database:totalUnknown:AVERAGE',
46       'DEF:totalAnalog=$database:totalAnalog:AVERAGE',

```

```

%hash = (
  'stats' => {
    'type' => {
      'laload' => [
        'DEF:laLoad5=$database:laLoad5:AVERAGE',
        'PRINT:laLoad5:AVERAGE:laLoad5=%1.2lf'
      ],
    },
  },
--snip--

```

We use the name of the database specified on /usr/local/nmis8/models/Common-database.nmis (in green)

```

Common-database.nmis
85 'rttMonLatestRtt' => '/nodes/$node/health/rttMonLatestRtt-$index.rrd',
86 'psuStatus' => '/nodes/$node/health/psuStatus-$index.rrd',
87 'fanStatus' => '/nodes/$node/health/fanStatus-$index.rrd',
88 'cbgqs-out' => '/nodes/$node/interface/sifDescr-out-$item.rrd',
89 'laload' => '/nodes/$node/health/laLoad.rrd',
90 'systemStats' => '/nodes/$node/health/systemStats.rrd',
91 'hr' => '/nodes/$node/health/hr.rrd',
92 'hrwin' => '/nodes/$node/health/hrwin.rrd',
93 'akcp_temp' => '/nodes/$node/misc/akcp-temp-$index.rrd',
94 'akcp_hum' => '/nodes/$node/misc/akcp-hum-$index.rrd',
95 'sessions' => '/nodes/$node/misc/sessions.rrd',
96 'ccpu' => '/nodes/$node/health/health.rrd',
97 'cssgroup' => '/nodes/$node/health/group-$index.rrd',
98 'csscontent' => '/nodes/$node/health/content-$index.rrd',
99 'hrsmncpu' => '/nodes/$node/health/hrsmncpu-$index.rrd',

```

Once we have created the threshold, it is time to tested. The best way to test if it is working as desired, is by running: /usr/local/nmis8/bin/nmis.pl and using debug=1

```
$ /usr/local/nmis8/bin/nmis.pl type=threshold debug=1 node=localhost
```

As we can see, the output show, that the threshold has been applied, in this case we see that the current value is 3.64 which has a current level of Critical because it has exceeded the threshold value of 2. (in green).

Note: I have put the system under stress to achieve a high load value. If you need to force your threshold to trigger, use a lower value in your threshold implementation (e.g. 0.01).

```
21:33:02 thresholdProcess, Proactive Interface Availability, Normal, , value=99.996 reset=70
21:33:02 doThreshold, section system, type laload has a threshold
21:33:02 doThreshold, threshold=laload_threshold found in section=system type=laload indexed=
21:33:02 runThrHld, WORKING ON Threshold for thrname=laload_threshold type=laload item=
21:33:02 getSummaryStats, Start type=laload, index=, start=-15 minutes, end=now
21:33:02 getFileName, filename of type=laload is /usr/local/nmis8/database/nodes/localhost/health/laload.rrd
21:33:02 getDBName, returning database name=/usr/local/nmis8/database/nodes/localhost/health/laload.rrd for sect=laload, index=, item=
21:33:02 runThrHld, processing threshold laload_threshold
21:33:02 getThresholdLevel, Start threshold=laload_threshold, index= item=
21:33:02 getThresholdLevel, found threshold=laload_threshold entry=default
21:33:02 getThresholdLevel, threshold=laload_threshold, item=laload5, value=3.64
21:33:02 getThresholdLevel, result threshold=laload_threshold, level=Critical, value=3.64, thrvalue=2, reset=0
21:33:02 thresholdProcess, Proactive System Load, Critical, , value=3.64 reset=0
21:33:02 notify, Start of Notify
21:33:02 notify, Finished
21:33:02 doThreshold, section system, type nodehealth has no threshold
```

And finally, go to NMIS GUI and check the event for the node "localhost", we can see that the alert has been created and is showing the details as expected.

localhost	00:05:05	23-Mar-2020 21:27:02	Proactive System Load	Critical		Value=3.64 Threshold=2	-1	active
-----------	----------	----------------------	-----------------------	----------	--	------------------------	----	--------

Now, we have set up properly our threshold for "Linux System Load"
